

Steinitz exchange lemma Let V be a vector space, and $L, S \subset V$ are finite such that

1. Elements of L are linearly independent;
2. The span of S is V .

Then, $|L| \leq |S|$ and there is a set $S' \subset S$ such that $|S'| = |S| - |L|$ and the span of $L \cup S'$ is V .

Proof Consider the sequence $T = S_1, \dots, S_{|S|}$. We do the following for each of $L_1, \dots, L_{|L|}$:

1. Append L_i to the beginning of T ;
2. Remove the last vector of T that is a linear combination of preceding vectors.

Neither of the steps changes the span of T (Lemma 1.23). Therefore, $L_i \in \text{span } T$, and adding L_i to T creates a linear dependence in T . This ensures that T has a dependent vector (Lemma 1.19), and it is not a vector of L , because they are only preceded by other vectors of L .

In the end, T will consist of L and $S' \subset S$ such that $|S'| = |S| - |L|$, and $\text{span } L \cup S' = \text{span } T = V$.
